(54) Title: A METHOD FOR PRODUCING CONTROLLED ASPECT RATIO RETICULATED CARBON FOAM AND THE RESULTANT FOAM

#### (57) Abstract

A method of manufacturing and the resultant reticulated open cell carbon foam with a controlled aspect ratio between 0.6 to 1.2 throughout the body of the foam billet by controlling the exothermic reaction of the resin system below the decomposition temperature of the foam.

WO 98/02382 PCT/US97/1204:

A METHOD FOR PRODUCING CONTROLLED ASPECT RATIO RETICULATED CARBON FOAM AND THE RESULTANT FOAM

Open cell vitreous carbon foam, also called reticulated vitreous carbon foam, is a vitreous carbon structure of three dimensional interconnected polyhedron 5 cells. Vitreous carbon is a glassy carbon as opposed to a graphitic carbon. A cell is typically comprised of 12 to 14 connected struts or ligaments which form a three dimensional polyhedron. An open cell is a cell where no film or solid is connected between the ligaments so that 10 there is free communication in to and out of a cell, and in a group of adjoining cells all cells are interconnected and form a three dimensional interconnected structure. An open cell foam has a structure which typically consists of three dimensional 15 interconnected polyhedron cells with 12 to 14 ligaments composing each cell, and each cell having a spheroidal shape.

20 The degree to which the cell shape approaches a perfectly spherical shape is measured by the aspect ratio. The aspect ratio is a dimensionless number, defined for the purpose of this patent application, as the diameter of the cell in the vertical direction divided by the diameter of the cell in the horizontal direction. A perfectly spherical cell would have an aspect ratio of 1.

The shape of the cell and hence the aspect ratio of the cell can effect the performance of the bulk vitreous carbon foam which is comprised of these cells. The strength of the bulk vitreous carbon and the resistance to flow of fluids through the bulk vitreous carbon are some of the physical properties of the bulk carbon foam affected by the aspect ratio.

5

20

25

Since the physical properties of carbon foam are affected by the aspect ratio, an aspect ratio of 1 would be required for a completely isotropic foam. Users of carbon foam often desire isotropic behavior from the foam and therefore desire a foam with an aspect ratio as close to 1 as possible, and find an aspect ratio between 0.6 to 1.2 acceptable for these purposes.

Vitreous carbon foam is often coated with other materials via a chemical vapor deposition process. If the underlying vitreous carbon foam has a vast majority of cells with aspect ratios greatly different than 1 the resultant coated foam will have cells with aspect ratios greatly different than 1 and the resultant coated foam may have anisotropic properties. Chemical vapor deposition is used to coat carbon foams with ceramics such as SiC or BN and metals such as W or Ta. One application of Ta coat carbon foam is invivo exoskeleton

15

20

U.S. Patent #5,282,861. In this particular application it has been found necessary to produce carbon foam billets at least 6" thick and as much as 8" thick where the cells of the carbon foam have an aspect ratio between 0.6 to 1.2. Therefore there is a demonstrated commercial need for vitreous carbon foam of thickness greater than 6" having cells with aspect ratios between 0.6 to 1.2.

PRIOR ART

Reticulated vitreous carbon open cell foam has been manufactured by first impregnating polyurethane open cell foam with carbonaceous thermal setting resins. The resin impregnating foam is then rapidly heated to some arbitrary curing temperature such as 100 C - 200 C to thermal set the resin. The thermal set impregnated foam is then heated to a suitable pyrolysis temperature, on the order of 800 C - 2000 C, in order to convert the carbonaceous resin in to vitreous carbon. Vinton et al, U.S. patent #4,022,875, discloses a method which endeavors to faithfully reproduce the cell geometry of the polyurethane foam precursor in the resultant vitreous carbon foam. This prior art method rapidly heats the resin impregnated foam to a curing temperature necessary to thermal set the resin. This prior art method makes no attempt to control the shape of the carbon foam cell but

10

15

20

25

targets faithful polyur thane foam geometry reproduction. Franklin U.S. patent 4,067,956 describes a method of producing an anisotropic vitreous carbon open cell foam which is compressed a minimum of 50% in only one direction. This patent physically compresses the foam a minimum of 50% in one direction during processing or uses a minimum of 50% compressed polyurethane foam precursor. The reason a minimum of 50% compression is required is that in the prior art methods a substantially uniform modification of the aspect ratio throughout the majority of the volume of the bulk foam could not be achieved unless a minimum of 50% compression or an aspect ratio of 0.5 or less was achieved.

Neither of aforementioned prior art patents discusses the temperature at which the carbonaceous resin undergoes an exothermic reaction and begins to crosslink and thermal set. Nor does this prior art discuss, control or employ this exotherm to specifically control or modify the cell shape within the resultant vitreous carbon foam. In the prior art attempts to faithfully reproduce the geometry of the polyurethane open cell foam precursor, this precursor typically has an aspect ratio of 1.4. In other prior art, the foam is physically compressed by at least 50 % in one direction, resulting in an aspect ratio less then or equal to 0.5.

## SUMMARY OF INVENTION

It is the object of the present invention to control the aspect ratio of the cells within the vitreous carbon foam to between 0.6 and 1.2. In the method of the 5 present invention a polyurethane open cell foam is first impregnated with a carbonaceous resin. The open cell polyurethane foam typically has a aspect ratio of 1.3 to 1.4. This aspect ratio is not faithfully reproduced but modified during the process of the present invention to 10 reach the desired aspect ratio of 0.6 to 1.2. The resin is comprised of a carbonaceous liquid such as furfuryl alcohol, furan or phenolic compounds, and an activating catalyst such as methyl para-toluene sulfonate, para-toluene sulfonic acid, citric acid and oxalic acid. 15 A preferred resin for the present invention is furfuryl alcohol carbonaceous liquid and methyl para-toluene sulfonate catalyst.

set in an exothermic reaction which takes place below the decomposition temperature of the polyurethane foam. In the present invention exotherm temperatures of the polyurethane foam impregnated with the carbonaceous resin system are measured and a curing curve specific to each polyurethane foam impregnated with carbonaceous resin system is devised. The curing is p rformed in an inert

atmosphere such as nitrogen or argon, or in a non-oxidizing atmosphere such as hydrogen, or in a vacuum. After curing, the piece is carbonized to vitreous carbon in an atmosphere, as described for curing, at a suitable temperature between 900° C to 3000° C. The curing and carbonization can be performed in the same process sequence.

The curing curve will be at a heat up rate which will control the amount of exothermic heat released 10 into the work piece at any given time and the curing curve will have specific holding temperatures at or before the exotherm temperature or temperatures in order to control the amount of heat released into a given work piece. The exotherm heat release holding temperatures are 15 typically between 50° C to 120° C. Uncontrolled exotherms can cause a melt down of an impregnated foam or cells with undesirable aspect ratios. Insufficient exotherms or endothermic reactions would not allow the polyurethane precursor cell to be modified. The curing curve heat up 20 rate may be controlled to 150° C to 200° C in order to fully crosslink the thermal setting resin.

The shape of the cells in the foam is modified

because the heat from the exothermic reaction softens the
ligaments which comprise the foam cells and the weight of
the impregnated foam compresses the cell from the

polyurethan precursor aspect ratio of 1.3 to 1.4 to the desired aspect ratio of 0.6 to 1.2. The modified shape is permanently set when the resin system fully crosslinks or thermal sets. When the resin system cross links it stiffens the cell ligaments. If the resin crosslinks too quickly the polyurethane cell can not be modified sufficiently or uniformly through the body of the work piece. In some cases a weight will be placed on top of the foam to facilitate cell modification. The weight will not compress the impregnated foam by more than 20% of its thickness.

A clearer understanding of the invention will be had by reference to the following description, drawings and examples.

25

# BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates, in general, the steps

and generalized apparatus for performing the method of
the present invention and which method maybe used for any
of the following examples;

Figure 2 is a graph illustrating the aspect ratio for one prior art foam material;

10 Figure 3 is a graph illustrating the aspect ratio for Example 1 of the present invention;

Figure 4 is a graph illustrating the aspect ratio for Example 2 of the present invention;

Figure 5 is a graph illustrating the aspect

15 ratio for Example 3 of the present invention;

Figure 6 illustrates an example of the resultant foam material produced by the method of the present invention.

# DETAILED DESCRIPTION OF THE INVENTION

The present invention will be described in detail with reference to three specific examples, all of which can be performed using the steps of the general method of Figure 1. Each example will have both specific times, temperatures, weights, etc. plus ranges for these

times, temperatures, weights, etc. in order to practice the present invention.

## Example 1

A carbonaceous resin 10 was mixed in Step 1 in a vessel 12 using furfuryl alcohol containing 1 part per hundred methyl para-toluene sulfonate (range 0.4% to 0.4% to 8% by weight methyl para-toluene sulfonate). A piece of polyurethane foam with cells having a diameter on the order of 0.023" with aspect ratios of 1.3 to 1.4 was impregnated in step 2 with the carbonaceous resin. Excess resin was removed from the impregnated foam work piece by pressing the piece on to a perforated wooden board. The infusion of the catalyzed furfuryl resin caused the polyurethane foam to swell.

The wet, uncured piece was then placed in a retort 16. In Step 3 the retort was filled with nitrogen and was heated with heater 18 at 0.16 degrees C per minute (range 0.05 ° C/min - 0.7° C/min) until it reach the exothermic heat release temperature of 70° C (range 50° C - 90° C). The piece was held at 70 C for 3 hrs. (range 1 to 15 hrs..) to allow the cell aspect ratio modification to take place. The piece was then heated at 0.09 degrees C per minute (range 0.03 ° C/min. - 0.13° C/min) until 170° C (range 150° C - 190° C). This second controlled ramp was n cessary to allow for the complete

10

15

thermal setting of the carbonaceous resin while allowing the exothermic heat of the thermal setting to dissipate without effecting the cell shape of the work piece. The furnace was allowed to cool to room temperature and the piece was removed.

In Step 4 the piece was then relocated to a high temperature furnace 20 and heated with heater 22 to 600° C (range 400° - 800°C) over a period of 30.3 hours (range 3 - 60 hrs..). The furnace was allowed to cool to room temperature and the piece was removed. In Step 5 the piece was then relocated in to a high temperature retort furnace 24 and fired with heater 26 from room temperature to 1100°C (range 900° C - 2200°C) over a period of 7 hours (range 5-56 hrs..) in order to carbonize the resin to a vitreous carbon. The furnace was allowed to cool and the product was removed. If desired, Steps 3, 4 and 5 may be performed sequentially within the same suitable furnace.

20

25

The resultant product of Example 1 was an open cell vitreous carbon piece with the vast majority of cells having an aspect ratio between 0.6 and 1.2 as shown in figure 3. The visual appearance of this product would be as shown in Figure 6.

The following two examples:

#### Example 2

A carbonaceous resin was mixed in Step 1 using furfuryl alcohol containing 2 part per hundred methyl paratoluene sulfonate. A piece of polyurethane foam with cells having a diameter on the order of 0.023" with aspect ratios of 1.3 to 1.4 was impregnated in Step 2 with the carbonaceous resin. Excess resin was removed from the impregnated foam work piece by pressing the piece on to a perforated wooden board. The infusion of the catalyzed furfuryl resin caused the polyurethane foam to swell.

The wet, uncured piece was then placed in a

retort. In Step 3 retort was filled with nitrogen and was
heated at .13 degrees C per minute until it reach the
exothermic heat release temperature of 60 C. The piece
was held at 60 C for 3 hrs. to allow the cell aspect
ratio modification to take place. The piece was then
heated at 0.1 degrees C per minute until 170 C. This
second controlled ramp was necessary to allow for the
complete thermal setting of the carbonaceous resin while
allowing the exothermic heat of the thermal setting to
dissipate without effecting the cell shape of the work
piece.

The furnace was allowed to cool to room temperature and the piece was removed. Step 4 was skipped for this Example 2. In Step 5 the piece was then relocated in to a high temperature retort furnace and fired from room temperature to 1100 C over a period of 36.5 hours in order to carbonize the resin to a vitreous carbon. The furnace was allowed to cool and the product was removed. If desired, steps 3 and 5 may be performed sequentially within the same suitable furnace.

10 The resultant product of Example 2 was an open cell vitreous carbon piece with vast majority of cells having an aspect ratio between 0.6 and 1.2 as shown in Figure 4.

The visual appearance of the product would be as shown in Fig. 6.

15

20

25

5

### Example 3

A carbonaceous resin was mixed in Step 1 using furfuryl alcohol containing 1 part per hundred methyl paratoluene sulfonate. A piece of polyurethane foam with cells having a diameter on the order of 0.023" with aspect ratios of 1.3 to 1.4 was impregnated in Step 2 with the carbonaceous resin. Excess resin was removed from the impregnated foam work piece by pressing the piece on to a perforated wooden board. The infusion of the catalyzed furfuryl resin caused the polyurethane foam to swell.

The wet, uncured piece was then placed in a retort. An uniform mass 28 (shown in Step 3 of Figure 1) such as a solid or perforated carbon plate was placed on top of the wet, uncured piece. The carbon plate was supported by the wet, uncured piece and compressed the piece 1% in the 5 thickness direction. In step 3 the retort was filled with nitrogen and was heated at 0.18 degrees C per minute until it reach the exothermic heat release temperature of 70 C. The piece was held at 70 C for 3 hrs. to allow the cell aspect ratio modification to take place. The piece 10 was then heated at 0.09 degrees C per minute until 170 C. This second controlled ramp was necessary to allow for the complete thermal setting of the carbonaceous resin while allowing the exothermic heat of the thermal setting to dissipate without effecting the cell shape of the work 15 piece. The furnace was allowed to cool to room temperature and the piece was removed. Step 4 was skipped for this Examples. In step 5 the piece was then relocated in to a high temperature retort furnace and fired from room temperature to 1100 C over a period of 36.5 hours in 20 order to carbonize the resin to a vitreous carbon. The furnace was allowed to cool and the product was removed.

The resultant of Example 3 product was an open

25 cell vitreous carbon piece with the vast majority of

cells having an aspect ratio between 0.8 and 1.2 as shown

in Figure 5. The visual appearance of the product would be as shown in Figure 6.

As these three examples show, the polyurethane foam precursor cell shape can be modified and controlled 5 by controlled heat up rates and exotherm heat release temperature holds. The heat up rate and hold temperature(s) depend on the carbonaceous liquid, the catalyst employed, the amount of catalyst used, and the amount of cell modification desired. On commercial size 10 pieces, all surfaces of the pyrolyzed product exhibit some distortion due to the pyrolysis process. After the pyrolysis process the distortion zones are trimmed away to yield a product with smooth faces. The bottom 5% to 10% of the smooth product may be modified below an aspect 15 ratio of 0.6 and the top 5% to 10% of the product may not be modified to an aspect ratio of 1.2 or less. However this area of the product is generally trimmed away to yield a more aesthetically pleasing product as shown in Figure 6. 20

Although the invention has been described with references to a particular embodiment, it is to be appreciated that various adaptations and modifications may be made and the invention is only to be limited by the appended claims.

# \_C\_L\_A\_I\_M\_S\_

I claim:

5

1. A method for producing reticulated carbon foam with a controlled aspect ratio between 0.6 to 1.2 including the following steps,

providing an open cell polyurethane foam,

10 providing a carbonaceous thermal setting resin with said
resin containing a controlled amount of well-mixed
catalyst,

impregnating the foam with the resin, curing the impregnated foam under a controlled curing cycle in an inert or reducing atmosphere or a 15 vacuum, wherein the controlled curing cycle includes a specific exotherm plateau temperature where the curing cycle is isothermally maintained for sufficient time to allow the first exothermic reaction of the thermal setting resin to release heat sufficient to soften the 20 polyurethane foam ligaments and allow said foam ligaments to assume the required shape to produce the desired aspect ratio and to begin crosslinking and wherein the now partially crosslinked impregnated foam continues on the controlled curing cycle along a controlled heat-up 25 ramp, until the r sin is fully cross linked and

pyrolyzing the crosslinked foam in an inert or reducing atmosphere or vacuum until the crosslinked resin is transformed into vitreous carbon foam with cells having the shape and aspect ratio between 0.6 to 1.2 created during the exothermic plateau provided during controlled curing cycle.

- 2. The method of claim 1 wherein the controlled curing cycle includes additional exotherm heat release plateau holding temperatures to allow for complete thermal setting of the resin.
- 3. The method of claim 1 wherein a uniformly distributed mass is provided and including the step of placing the mass on top of and supported by the impregnated foam before the controlled curing, to compress the impregnated foam between 0% to 20%.
- 4. A process as recited in claim 1 wherein a

  20 cover is provided and including the step of placing the
  cover on top of the impregnated foam and supported by the
  impregnated foam before the controlled curing to compress
  the impregnated foam between 0% to 20%.

5. A method for producing reticulated carbon foam with a controlled aspect ratio between 0.6 to 1.2 including the following steps,

providing an open cell polyurethane foam, providing

a furfuryl alcohol with said furfuryl alcohol containing

0.4% to 8% by weight methyl para-toluene sulfonate to

form a resin,

impregnating the foam with the resin,

curing the impregnated foam under a controlled

curing cycle in an inert or reducing atmosphere or a

vacuum wherein the controlled curing cycle includes

heating at a rate between .05° C/min to 0.7° C/min to an

exotherm plateau temperature between 50° C to 90° C

wherein the curing cycle is isothermally maintained for 1

to 15 hours to allow the first exothermic reaction of the

thermal setting resin to release heat sufficient to

soften the polyurethane foam ligaments and allow said

foam ligaments to assume the required shape to produce

the desired aspect ratio and to begin crosslinking and

wherein

the now partially crosslinked impregnated foam continues on the controlled curing cycle along a controlled heat-up ramp, at a rate of between .03 C/min to 0.13 C/min to a temperature between 150° C to 190° C until the resin is fully cross linked,

pyrolyzing the crosslinked foam to a temperature between 900 C to 1400 C in an inert or

10

en elegant en la caracteria de la companya della co

reducing atmosphere or a vacuum until the crosslinked resin is transformed into vitreous carbon foam with cells having the shape and aspect ratio between 0.6 to 1.2 created during the exothermic plateau provided during the controlled curing cycle.

- 6. The method of claim 5 wherein after the foam is heated to the exotherm plateau temperatures the foam is heated to a temperature between 400° to 800° C for a period between 3 to 60 hours before the foam is pyrolyzed.
- 7. The method of claim 5 wherein a uniformly distributed mass is provided and including the step of placing the mass on top of and supported by the 15 impregnated foam before the controlled curing to compress the impregnated foam between 0% to 20%.
- 8. The method of claim 5 wherein a cover is pr ovided and including the step of placing the on top of 20 the impregnated foam and supported by the impregnated foam before the controlled curing to compress the impregnated foam between 0% to 20%.

areas in a survival particular and the second of the second

- 9. A reticulated carbon foam, including an open cell structure formed of these dimensional interconnected polyhedron cells formed by a vitreous carbon,
- a substantial number of the cells each

  comprised of 12 to 14 interconnected ligaments to form a
  three dimensional polyhedron,

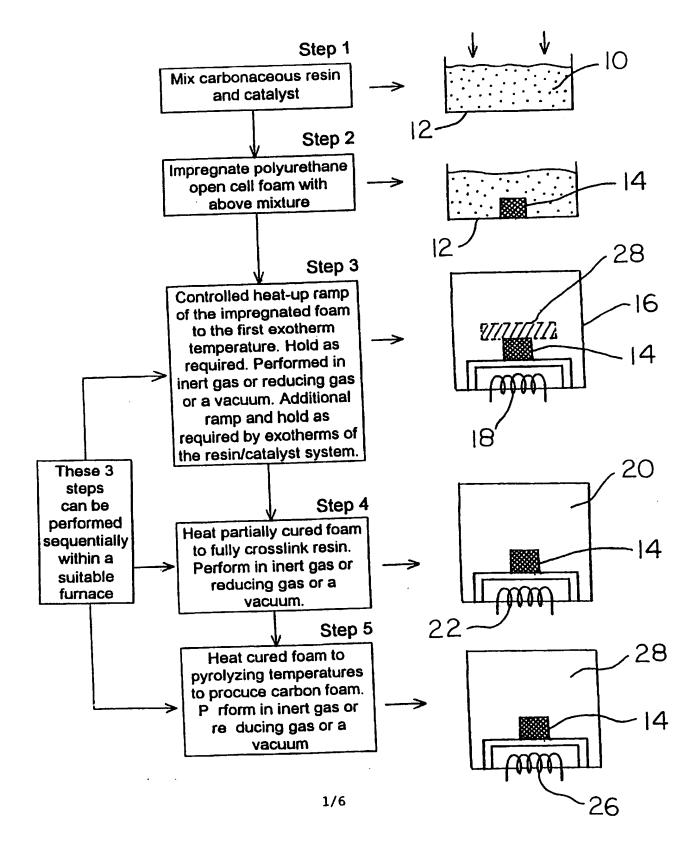

each cell having an aspect ratio defined by the diameter of the cell in a vertical direction divided by the diameter of the cell in the horizontal direction, and a substantial number of the cells in the open cell structure having an aspect ratio between 0.6 to 1.2.

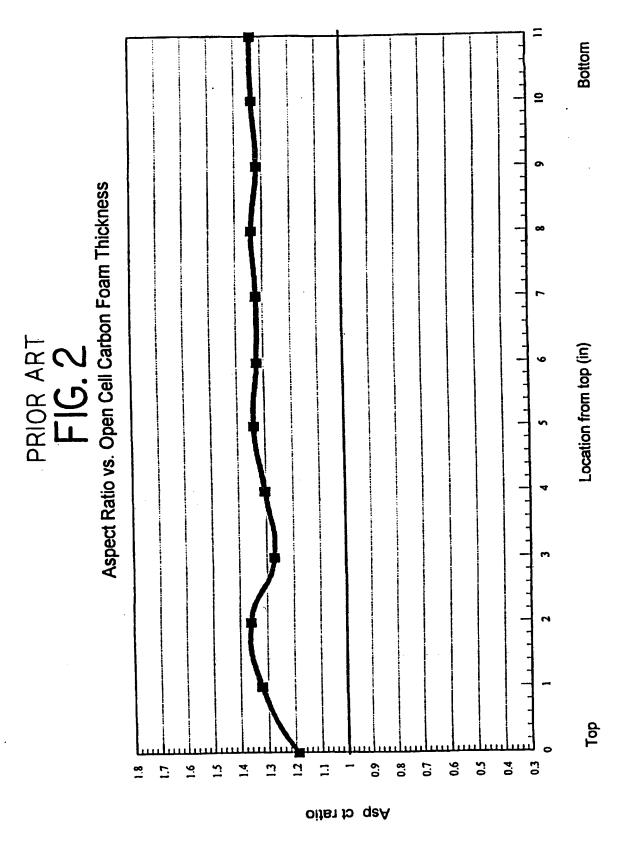

10. The reticulated carbon foam of claim 9 wherein the open cell structure is substantially isotropic in configuration.
